(54) Title: DEACETYLASE INHIBITORS

(57) Abstract: The present invention provides hydroxamate compounds which are deacetylase inhibitors. The compounds are suitable for pharmaceutical compositions having anti-proliferative properties.

## DEACETYLASE INHIBITORS

The present invention relates to hydroxamate compounds which are inhibitors of histone deacetylase. The inventive compounds are useful as pharmaceuticals for the treatment of proliferative diseases.

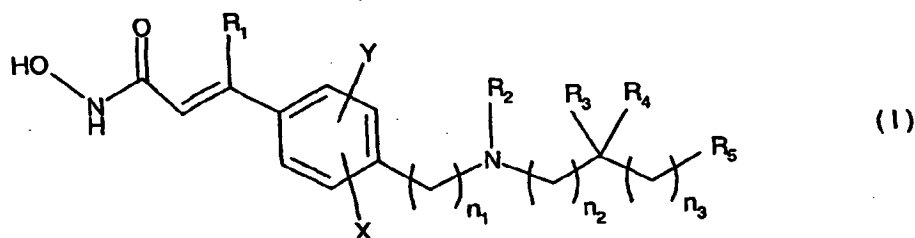

### Background

Reversible acetylation of histones is a major regulator of gene expression that acts by altering accessibility of transcription factors to DNA. In normal cells, histone deacetylase (HDA) and histone acetyltransferase together control the level of acetylation of histones to maintain a balance. Inhibition of HDA results in the accumulation of hyperacetylated histones, which results in a variety of cellular responses.

Inhibitors of HDA have been studied for their therapeutic effects on cancer cells. For example, butyric acid and its derivatives, including sodium phenylbutyrate, have been reported to induce apoptosis *in vitro* in human colon carcinoma, leukemia and retinoblastoma cell lines. However, butyric acid and its derivatives are not useful pharmacological agents because they tend to be metabolized rapidly and have a very short half-life *in vivo*. Other inhibitors of HDA that have been widely studied for their anti-cancer activities are trichostatin A and trapoxin. Trichostatin A is an antifungal and antibiotic and is a reversible inhibitor of mammalian HDA. Trapoxin is a cyclic tetrapeptide, which is an irreversible inhibitor of mammalian HDA. Although trichostatin and trapoxin have been studied for their anti-cancer activities, the *in vivo* instability of the compounds makes them less suitable as anti-cancer drugs. There remains a need for an active compound that is suitable for treating tumors, including cancerous tumors, that is highly efficacious and stable.

### Summary

As is evident to those skilled in the art, the many of the deacetylase inhibitor compounds of the present invention contain asymmetric carbon atoms. It should be understood, therefore, that the individual stereoisomers are contemplated as being included within the scope of this invention.

The hydroxamate compounds of the present invention can be produced by known organic synthesis methods. For example, the hydroxamate compounds can be produced

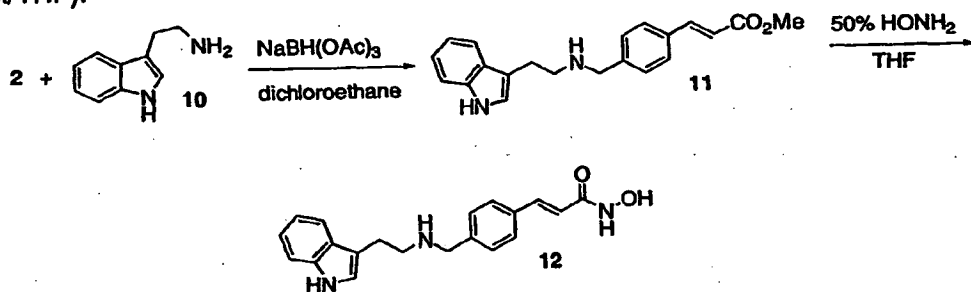

by reacting methyl 4-formyl cinnamate with tryptamine and then converting the reactant to the hydroxamate compounds. As an example, methyl 4-formyl cinnamate **2**, is prepared by acid catalyzed esterification of 4-formylcinnamic acid **3** (Bull. Chem. Soc. Jpn. 1995; 68:2355-2362). An alternate preparation of methyl 4-formyl cinnamate **2** is by a Pd-catalyzed coupling of methyl acrylate **4** with 4-bromobenzaldehyde **5**.

Additional starting materials can be prepared from 4-carboxybenzaldehyde **6**, and an exemplary method is illustrated for the preparation of aldehyde **9**, shown below. The carboxylic acid in 4-carboxybenzaldehyde **6** can be protected as a silyl ester (e.g., the *t*-butyldimethylsilyl ester) by treatment with a silyl chloride (e.g., *t*-butyldimethylsilyl chloride) and a base (e.g., triethylamine) in an appropriate solvent (e.g., dichloromethane). The resulting silyl ester **7** can undergo an olefination reaction (e.g., a Horner-Emmons olefination) with a phosphonate ester (e.g., triethyl 2-phosphonopropionate) in the presence of a base (e.g., sodium hydride) in an appropriate solvent (e.g., tetrahydrofuran (THF)). Treatment of the resulting diester with acid (e.g., aqueous hydrochloric acid) results in the hydrolysis of the silyl ester providing acid **8**. Selective reduction of the carboxylic acid of **8** using, for example, borane-dimethylsulfide complex in a solvent (e.g., THF) provides an intermediate alcohol. This intermediate alcohol could be oxidized to aldehyde **9** by a number of known methods, including, but not limited to, Swern oxidation, Dess-Martin periodinane oxidation, Moffatt oxidation and the like.

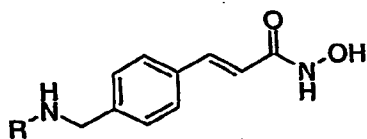

The aldehyde starting materials **2** or **9** can be reductively aminated to provide secondary or tertiary amines. This is illustrated by the reaction of methyl 4-formyl cinnamate **2** with tryptamine **10** using sodium triacetoxyborohydride ( $\text{NaBH}(\text{OAc})_3$ ) as the reducing agent in dichloroethane (DCE) as solvent to provide amine **11**. Other reducing agents can be used, e.g., sodium borohydride ( $\text{NaBH}_4$ ) and sodium cyanoborohydride ( $\text{NaBH}_3\text{CN}$ ), in other solvents or solvent mixtures in the presence or absence of acid catalysts (e.g., acetic acid and trifluoroacetic acid). Amine **11** can be converted directly to hydroxamic acid **12** by treatment with 50% aqueous hydroxylamine in a suitable solvent (e.g., THF in the presence of a base, e.g.,  $\text{NaOH}$ ). Other methods of hydroxamate formation are known and include reaction of an ester with hydroxylamine hydrochloride and a base (e.g., sodium hydroxide or sodium methoxide) in a suitable solvent or solvent mixture (e.g., methanol, ethanol or methanol/THF).

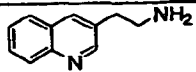

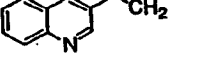

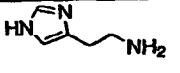

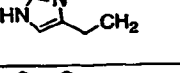

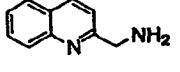

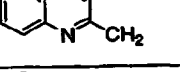

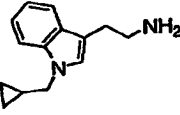

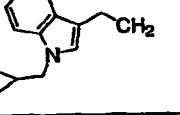

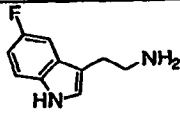

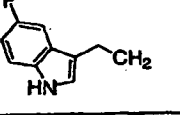

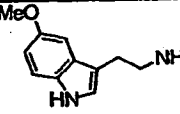

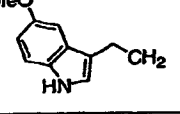

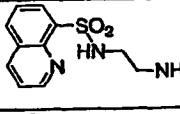

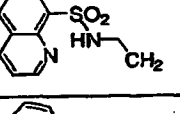

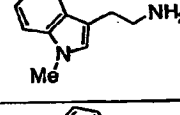

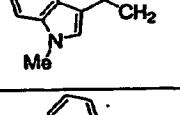

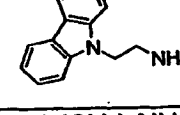

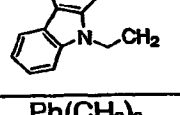

Aldehyde **2** can be reductively aminated with a variety of amines, exemplified by, but not limited to, those illustrated in Table 1. The resulting esters can be converted to target hydroxamates by the methods listed.

An alternate synthesis of the compounds of this invention starts by reductive amination of 4-formyl cinnamic acid **3**, illustrated below with 3-phenylpropylamine **13**, using, for example,  $\text{NaBH}_3\text{CN}$  as the reducing agent in MeOH and HOAc as a catalyst. The basic nitrogen of the resulting amino acid **14** can be protected, for example, as *t*-butoxycarbamate (BOC) by reaction with di-*t*-butyldicarbonate to give **15**.

The carboxylic acid can be coupled with a protected hydroxylamine (e.g., *O*-trityl hydroxylamine) using a dehydrating agent (e.g., 1-(3-dimethylaminopropyl)-3-ethylcarbodiimide hydrochloride (EDCI)) and a catalyst (e.g., 1-hydroxybenzotriazole hydrate (HOBT)) in a suitable solvent (e.g., DMF) to produce **16**. Treatment of **16** with a strong acid (e.g., trifluoroacetic acid (TFA)) provides a hydroxamic acid **17** of the present invention. Additional examples of compounds that can be prepared by this method are:

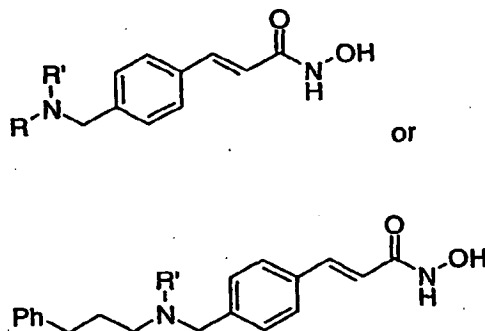

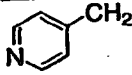

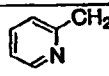

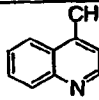

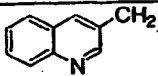

Tertiary amine compounds can be prepared by a number of methods. Reductive amination of **30** with nicotinaldehyde **32** using  $\text{NaBH}_3\text{CN}$  as the reducing agent in dichloroethane and HOAc as a catalyst provides ester **34**. Other reducing agents can be used (e.g.,  $\text{NaBH}_4$  and  $\text{NaBH}(\text{OAc})_3$ ) in other solvents or solvent mixtures in the presence or absence of acid catalysts (e.g., acetic acid, trifluoroacetic acid and the like). Reaction of ester **34** with  $\text{HONH}_2 \cdot \text{HCl}$ , NaOH in MeOH provides hydroxamate **36**.

Tertiary amine compounds prepared by this methodology are exemplified, but not limited to, those listed in Table 2.

An alternate method for preparing tertiary amines is by reacting a secondary amine with an alkylating agent in a suitable solvent in the presence of a base. For example, heating a dimethylsulfoxide (DMSO) solution of amine 11 and bromide 40 in the presence of (*i*-Pr)<sub>2</sub>NEt yielded tertiary amine 42. Reaction of the tertiary amine 42 with HONH<sub>2</sub>•HCl, NaOH in MeOH provides hydroxamate 43. The silyl group can be removed by any method

known to those skilled in the art. For example, the hydroxamate **43** can be treated with an acid, e.g., trifluoroacetic acid, or fluoride to produce hydroxyethyl compound **44**.

The hydroxamate compound, or salt thereof, is suitable for preparing pharmaceutical compositions, especially pharmaceutical compositions having deacetylase, especially histone deacetylase, inhibiting properties. Studies with athymic mice demonstrate that the hydroxamate compound causes HDA inhibition and increased histone acetylation *in vivo*, which triggers changes in gene expression that correlate with tumor growth inhibition.

The present invention further includes pharmaceutical compositions comprising a pharmaceutically effective amount of one or more of the above-described compounds as active ingredient. Pharmaceutical compositions according to the invention are suitable for enteral, such as oral or rectal, and parenteral administration to mammals, including man, for the treatment of tumors, alone or in combination with one or more pharmaceutically acceptable carriers.

The hydroxamate compound is useful in the manufacture of pharmaceutical compositions having an effective amount the compound in conjunction or admixture with excipients or carriers suitable for either enteral or parenteral application. Preferred are tablets and gelatin capsules comprising the active ingredient together with (a) diluents; (b) lubricants, (c) binders (tablets); if desired, (d) disintegrants; and/or (e) absorbents, colorants, flavors and sweeteners. Injectable compositions are preferably aqueous isotonic solutions or suspensions, and suppositories are advantageously prepared from fatty emulsions or suspensions. The compositions may be sterilized and/or contain adjuvants,

such as preserving, stabilizing, wetting or emulsifying agents, solution promoters, salts for regulating the osmotic pressure and/or buffers. In addition, the compositions may also contain other therapeutically valuable substances. The compositions are prepared according to conventional mixing, granulating or coating methods, respectively, and contain preferably about 1 to 50% of the active ingredient.

Suitable formulations also include formulations for parenteral administration include aqueous and non-aqueous sterile injection solutions which may contain antioxidants, buffers, bacteriostats and solutes which render the formulation isotonic with the blood of the intended recipient; and aqueous and non-aqueous sterile suspensions which may include suspending agents and thickening agents. The formulations may be presented in unit-dose or multi-dose containers, for example, sealed ampules and vials, and may be stored in a freeze-dried (lyophilized) condition requiring only the addition of the sterile liquid carrier, for example, water for injections, immediately prior to use. Extemporaneous injection solutions and suspensions may be prepared from sterile powders, granules and tablets of the kind previously described.

As discussed above, the compounds of the present invention are useful for treating proliferative diseases. A proliferative disease is mainly a tumor disease (or cancer) (and/or any metastases). The inventive compounds are particularly useful for treating a tumor which is a breast cancer, genitourinary cancer, lung cancer, gastrointestinal cancer, epidermoid cancer, melanoma, ovarian cancer, pancreas cancer, neuroblastoma, head and/or neck cancer or bladder cancer, or in a broader sense renal, brain or gastric cancer; in particular (i) a breast tumor; an epidermoid tumor, such as an epidermoid head and/or neck tumor or a mouth tumor; a lung tumor, for example a small cell or non-small cell lung tumor; a gastrointestinal tumor, for example, a colorectal tumor; or a genitourinary tumor, for example, a prostate tumor (especially a hormone-refractory prostate tumor); or (ii) a proliferative disease that is refractory to the treatment with other chemotherapeutics; or (iii) a tumor that is refractory to treatment with other chemotherapeutics due to multidrug resistance.

In a broader sense of the invention, a proliferative disease may furthermore be a hyperproliferative condition such as leukemias, hyperplasias, fibrosis (especially pulmonary, but also other types of fibrosis, such as renal fibrosis), angiogenesis, psoriasis,

atherosclerosis and smooth muscle proliferation in the blood vessels, such as stenosis or restenosis following angioplasty.

Where a tumor, a tumor disease, a carcinoma or a cancer are mentioned, also metastasis in the original organ or tissue and/or in any other location are implied alternatively or in addition, whatever the location of the tumor and/or metastasis.

The compound is selectively toxic or more toxic to rapidly proliferating cells than to normal cells, particularly in human cancer cells, e.g., cancerous tumors, the compound has significant antiproliferative effects and promotes differentiation, e.g., cell cycle arrest and apoptosis. In addition, the hydroxamate compound induces p21, cyclin-CDK interacting protein, which induces either apoptosis or G1 arrest in a variety of cell lines.

The following examples are intended to illustrate the invention and are not to be construed as being limitations thereto.

#### Example P1

Preparation of *N*-Hydroxy-3-[4-[[[2-(1*H*-indol-3-yl)-ethyl]-amino]methyl]phenyl]-2*E*-2-propenamide.

4-formylcinnamic acid methylester is produced by adding 4-formylcinnamic acid (25 g, 0.143 mol) in MeOH and HCl (6.7 g, 0.18 mol). The resulting suspension is heated to reflux for 3 hours, cooled and evaporated to dryness. The resulting yellow solid is dissolved in EtOAc, the solution washed with saturated NaHCO<sub>3</sub>, dried (MgSO<sub>4</sub>) and evaporated to give a pale yellow solid which is used without further purification (25.0 g, 92%). To a solution of tryptamine (16.3 g, 100 mmol) and 4-formylcinnamic acid methylester (19 g, 100 mmol) in dichloroethane, NaBH(OAc)<sub>3</sub> (21 g, 100 mmol) is added. After 4 hours the mixture is diluted with 10% K<sub>2</sub>CO<sub>3</sub> solution, the organic phase separated and the aqueous solution extracted with CH<sub>2</sub>Cl<sub>2</sub>. The combined organic extracts are dried (Na<sub>2</sub>SO<sub>4</sub>), evaporated and the residue purified by flash chromatography to produce 3-(4-[[[2-(1*H*-indol-3-yl)-ethylamino]methyl]-phenyl]-(2*E*)-2-propenoic acid methyl ester (29 g). A solution of KOH (12.9 g 87%, 0.2 mol) in MeOH (100 mL) is added to a solution of HONH<sub>2</sub>•HCl (13.9 g, 0.2 mol) in MeOH (200 mL) and a precipitate results. After 15 minutes the mixture is filtered, the filter cake

washed with MeOH and the filtrate evaporated under vacuum to approximately 75 mL. The mixture is filtered and the volume adjusted to 100 mL with MeOH. The resulting solution 2M HONH<sub>2</sub> is stored under N<sub>2</sub> at -20° C for up to 2 weeks. Then 3-(4-[[2-(1*H*-indol-3-yl)-ethylamino]-methyl]-phenyl)-(2*E*)-2-propenoic acid methyl ester (2.20 g, 6.50 mmol) is added to 2 M HONH<sub>2</sub> in MeOH (30 mL, 60 mmol) followed by a solution of KOH (420 mg, 6.5 mmol) in MeOH (5 mL). After 2 hours dry ice is added to the reaction and the mixture is evaporated to dryness. The residue is dissolved in hot MeOH (20 mL), cooled and stored at -20 °C overnight. The resulting suspension is filtered, the solids washed with ice cold MeOH and dried under vacuum, producing *N*-Hydroxy-3-[4-[[[2-(1*H*-indol-3-yl)-ethyl]-amino]methyl]phenyl]-2*E*-2-propenamide (*m/z* 336 [MH<sup>+</sup>]).

#### Example P2

Preparation of *N*-Hydroxy-3-[4-[[[2-(hydroxyethyl)[2-(1*H*-indol-3-yl)-ethyl]-amino]methyl]phenyl]-2*E*-2-propenamide

A solution of 3-(4-[[2-(1*H*-indol-3-yl)-ethylamino]-methyl]-phenyl)-(2*E*)-2-propenoic acid methyl ester (12.6 g, 37.7 mmol), (2-bromoethoxy)-*tert*-butyldimethylsilane (12.8 g, 53.6 mmol), (*i*-Pr)<sub>2</sub>NEt, (7.42 g, 57.4 mmol) in DMSO (100 mL) is heated to 50° C. After 8 hours the mixture is partitioned with CH<sub>2</sub>Cl<sub>2</sub>/H<sub>2</sub>O. The organic layer is dried (Na<sub>2</sub>SO<sub>4</sub>) and evaporated. The residue is chromatographed on silica gel to produce 3-[4-[[[2-(*tert*-butyldimethylsilyloxy)-ethyl]-[2-(1*H*-indol-3-yl)-ethyl]-amino]-methyl]-phenyl]-(2*E*)-2-propenoic acid methyl ester (13.1 g). Following the procedure described for the preparation of the hydroxamate compound in Example P1, 3-[4-[[[2-(*tert*-butyldimethylsilyloxy)-ethyl]-[2-(1*H*-indol-3-yl)-ethyl]-amino]-methyl]-phenyl]-(2*E*)-2-propenoic acid methyl ester (5.4 g, 11 mmol) is converted to *N*-hydroxy-3-[4-[[[2-(*tert*-butyldimethylsilyloxy)-ethyl]-[2-(1*H*-indol-3-yl)-ethyl]-amino]-methyl]-phenyl]-(2*E*)-2-propenamide (5.1 g,) and used without further purification. The hydroxamic acid (5.0 g, 13.3 mmol) is then dissolved in 95% TFA/H<sub>2</sub>O (59 mL) and heated to 40 - 50 °C for 4 hours. The mixture is evaporated and the residue purified by reverse phase HPLC to produce *N*-Hydroxy-3-[4-[[[2-(hydroxyethyl)[2-(1*H*-indol-3-yl)-ethyl]-amino]methyl]phenyl]-2*E*-2-propenamide as the trifluoroacetate salt (*m/z* 380 [MH<sup>+</sup>]).

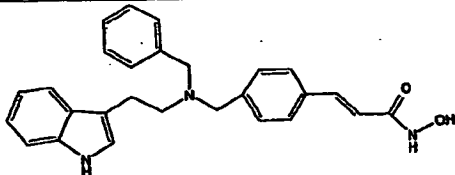

**Example P3**

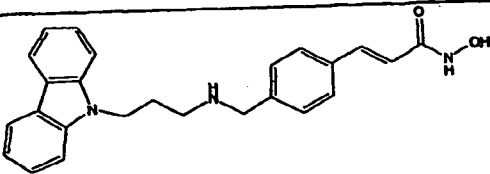

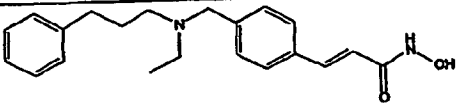

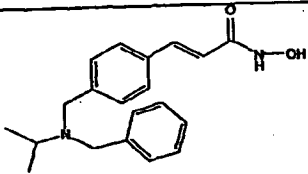

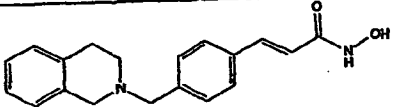

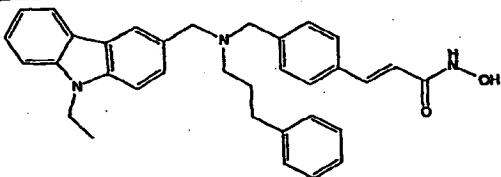

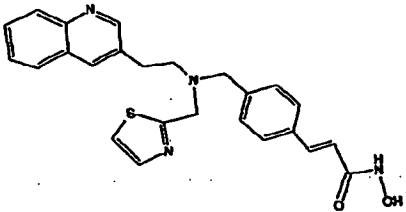

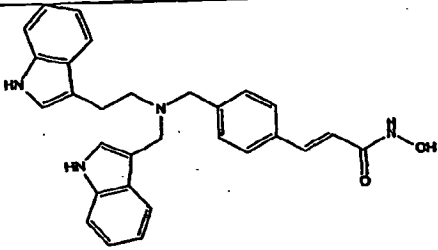

Preparation of N-hydroxy-3-[4-[[[2-(2-methyl-1*H*-indol-3-yl)-ethyl]-amino]methyl]phenyl]-2*E*-2-propenamide.

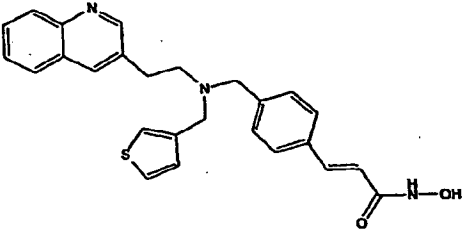

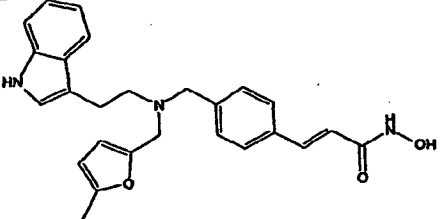

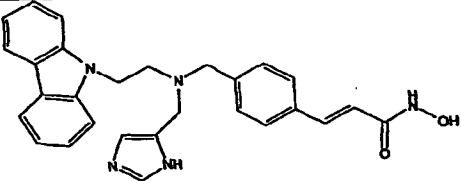

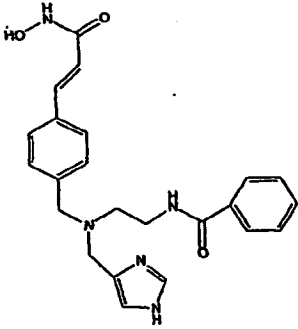

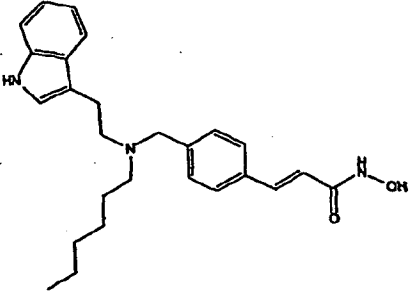

A suspension of LiAlH<sub>4</sub> (17 g, 445 mmol) in dry THF (1000 mL) is cooled to 0 °C and 2-methylindole-3-glyoxylamide (30 g, 148 mmol) is added in portions over 30 min. The mixture is stirred at room temperature for 30 min. and then maintained at reflux for 3 h. The reaction is cooled to 0 °C and treated with H<sub>2</sub>O (17ml), 15% NaOH (aq., 17ml) and H<sub>2</sub>O (51ml). The mixture is treated with MgSO<sub>4</sub>, filtered and the filtrate evaporated to give 2-methyltryptamine which is dissolved in MeOH. Methyl 4-formylcinnamate (16.9 g, 88.8 mmol) is added to the solution, followed by NaBH<sub>3</sub>CN (8.4 g) and AcOH (1 equiv.). After 1h the reaction is diluted with NaHCO<sub>3</sub> (aq.) and extracted with EtOAc. The organic extracts are dried (MgSO<sub>4</sub>), filtered and evaporated. The residue is purified by chromatography to give 3-(4-[[2-(2-methyl-1*H*-indol-3-yl)-ethylamino]-methyl]-phenyl)-(2*E*)-2-propenoic acid methyl ester. The ester is dissolved in MeOH, 1.0 M HCl/dioxane (1 – 1.5 equiv.) is added followed by Et<sub>2</sub>O. The resulting precipitate is filtered and the solid washed with Et<sub>2</sub>O and dried thoroughly to give 3-(4-[[2-(2-methyl-1*H*-indol-3-yl)-ethylamino]-methyl]-phenyl)-(2*E*)-2-propenoic acid methyl ester hydrochloride. 1.0 M NaOH (aq., 85 mL) is added to an ice cold solution of the methyl ester hydrochloride (14.9 g, 38.6 mmol) and HONH<sub>2</sub> (50% aq. solution, 24.0 mL, ca. 391.2 mmol). After 6 h, the ice cold solution is diluted with H<sub>2</sub>O and NH<sub>4</sub>Cl (aq., 0.86 M, 100 mL). The resulting precipitate is filtered, washed with H<sub>2</sub>O and dried to afford N-hydroxy-3-[4-[[[2-(2-methyl-1*H*-indol-3-yl)-ethyl]-amino]methyl]phenyl]-2*E*-2-propenamide (m/z 350 [MH<sup>+</sup>]).

#### Example B1

Cell lines H1299 (human lung carcinoma cell) and HCT116 (colon tumor cell) are obtained from the American Type Culture Collection, Rockville, MD. The cell lines are free of *Mycoplasma* contamination (Rapid Detection System by Gen-Probe, Inc., San Diego, CA) and viral contamination (MAP testing by MA BioServices, Inc., Rockville, MD). The cell lines are propagated and expanded in RPMI 1640 medium containing 10% heat-inactivated FBS (Life Technologies, Grand Island, NY). Cell expansions for implantation are performed in cell factories (NUNC, purchased from Fisher Scientific, Springfield, NJ). Cells are harvested at 50-90% confluency, washed once with HBSS (Hank's Balanced Salt Solution) containing 10% FBS, and suspended in 100% HBSS.

Cell proliferation is measured with a commercial MTS kit (Promega, Madison, Wis.) assay using an adaptation of published procedures, for example, that disclosed in *Feasibility of drug screening with panels of human tumor cell lines using a microculture tetrazolium assay*, Alley MC, et al., Cancer Res. 1988; 48:589-601. Cells are plated in 96-well tissue culture dishes, with top and bottom rows left empty. H1299 and HCT116 cells

are suspended in complete media at a density of  $5.3 \times 10^3$  and  $3.6 \times 10^3$  cell/mL, respectively, and 190  $\mu$ L are added per well. Each cell line is added to one half of the plate. Complete medium (200  $\mu$ L) is added to the top and bottom rows. Twenty-four hours later, 10  $\mu$ L of MTS solution is added to one of the plates to determine the activity at the time of compound addition ( $T_0$ ). The plate is incubated at 37 °C for 4 hours and the  $OD_{490}$  is measured on a Molecular Devices Thermomax at 490 nm using the Softmax program. The  $T_0$  plate serves as a reference for initial activity at the beginning of the experiment.

Five serial dilutions (1:4) of each compound are made in a 96-deep well plate with the highest concentrations on the edge of plate. Two cell lines are tested with two compounds per plate. Ten microliters of each of the five dilutions are added in triplicate and complete medium alone is added to columns six and seven. The plates are incubated at 37 °C for 72 hours. The MTS solution is added (as for the  $T_0$  plate) and read four hours later.

In order to analyze the data, the average background value (media alone) is subtracted from each experimental well; the triplicate values are averaged for each compound dilution. The following formulas are used to calculate percent growth.

$$\text{If } X > T_0, \% \text{ Growth} = ((X - T_0) / (GC - T_0)) \times 100$$

$$\text{If } X < T_0, \% \text{ Growth} = (X - T_0) / T_0 \times 100$$

in which  $T_0$  = (average value of cell viability at time 0) – background

GC = average value of untreated cells (in triplicate) – background

X = average value of compound treated cells (in triplicate) – background

The "% Growth" is plotted against compound concentration and used to calculate  $IC_{50}$ s employing the linear regression techniques between data points to predict the concentration of compounds at 50% inhibition.

The stock solution is diluted with 5% dextrose injection, USP, just prior to dosing. In addition, N-(2-aminophenyl)-4-[N-pyridin-3-yl]methoxycarbonylaminoethyl]benzamide is synthesized in accordance with Example 48 of EP 0 847 992 and used as a control compound (CMDC). Inhibition of cell growth in monolayer for 72 hours of compound treatment is measured in

triplicate experiments and used to derive the  $IC_{50}$  by MTS assay. The results are shown in Table B1.

The results show that the hydroxamate compounds of the present invention are highly active in inhibition of tumor cell growth. In addition to the above results, it has been observed that the compounds selectively inhibited tumor cells while showing minimal inhibition activities in non-tumorous cells.

The cells treated with the hydroxamate compounds are also tested for the induction of p21 promoter, which is a key mediator of G1 arrest and differentiation. The hydroxamate compounds activate the p21 promoter to a readily detectable level at a concentration within two-fold of their respective  $IC_{50}$  for monolayer cell growth inhibition in H1299. Without being bound by any particular theory, the correlation appears to demonstrate that HDA inhibition leads to transcriptional activation of genes that inhibit tumor cell proliferation.

#### **Example B2**

HDA is partially purified from H1299, human non-small cell lung carcinoma cells (obtained from American Type Culture Collection, 12301 Parklawn Drive, Rockville, MD 20852, USA). Cells are grown to 70-80% confluence in RPMI media in the presence of 10% FCS, harvested and lysed by sonication. The lysate is centrifuged at 23,420g for 10-15 min, the supernatant is applied to a Hiload 26/10 High performance Q-sepharose column (Amersham Pharmacia Biotech), and equilibrated with a buffer containing 20 mM Tris

pH 8.0, 1 mM EDTA, 10 mM  $\text{NH}_4\text{Cl}_2$ , 1 mM  $\beta$ -Mercaptoethanol, 5% glycerol, 2  $\mu\text{g/mL}$  aprotinin, 1  $\mu\text{g/mL}$  leupeptin, and 400 mM PMSF. Proteins are eluted in 4 mL aliquotes with a linear gradient from 0-500 mM NaCl in the above buffer at a flow rate of 2.5 mL/min. Each preparation of partially purified HDA enzyme is titrated to determine the optimal amount needed to obtain a signal to noise ratio of at least 5 to 1. Generally, 20-30  $\mu\text{L}$  of partially purified HDA (5-10 mg protein/mL) is mixed with 2  $\mu\text{L}$  of compound solution in DMSO in a deep well titer plate (Beckman). The compounds are serially diluted in DMSO to generate stocks at 20-fold of the assay concentrations. Final concentrations of compounds in the assay are 10  $\mu\text{M}$ , 2  $\mu\text{M}$ , 400 nM, 80 nM, and 16 nM with the final percentage of DMSO in each enzyme reaction equaling 0.1%. Each concentration of compound is assayed in duplicate. The substrate used in the reaction is a peptide of amino acid sequence, SGRGKGGKGLGKGGAKRHRKVLRD, corresponding to the twenty-four N-terminal amino acids of human histone H4, biotinylated at the N-terminus and penta-acetylated, at each lysine residue with  $^3\text{H}$ -acetate. To initiate the reaction, the substrate is diluted in 10  $\mu\text{L}$  of Buffer A (100 mM Tris pH 8.0, 2 mM EDTA), added to the enzyme mixture and collected at the bottom of the deep well plate by centrifugation for 5 minutes at 1500 rpm. Following centrifugation, the mixture is incubated at 37 °C for 1.5 hr. The reaction is stopped by the addition of 20  $\mu\text{L}$  of the Stop Buffer (0.5N HCl, 0.08M Acetic Acid). At this point, the assay proceeds to the robotic extraction phase or is frozen for several days at -80 °C.

The extraction of enzymatically cleaved  $^3\text{H}$ -acetate groups from the reaction mixture is achieved with the solvent TBME (t-butyl methyl ether) using the Tomtec Quadra 96 workstation. A program is written to add 200  $\mu\text{L}$  of TBME to a 96 "deep well" plate. The workstation is programmed to aspirate 50  $\mu\text{L}$  of air followed by 200  $\mu\text{L}$  of TBME and finally another 25  $\mu\text{L}$  of air, which is dispensed into the each well of the plate. The contents of the deep well were mixed thoroughly by pipetting 160  $\mu\text{L}$  up and down 10 times. Before addition of TBME to the reaction mixture, it is necessary to "pre-wet" the pipette tips with TBME to prevent the solvent from dripping during the transfer to the deep well plate. The organic and aqueous phases in the deep well are separated by centrifugation at 1500 rpm for 5 min. Opti-Phase Supermix liquid scintillation cocktail (200  $\mu\text{L}$ ) (Wallac) is added to each well of the 96-well Trilux plate (Wallac). The deep well and Trilux plates are placed back on the workstation programmed to aspirate 25  $\mu\text{L}$  of air into the pipette tips followed by 100  $\mu\text{L}$  of the upper TBME phase and transfer it into the Trilux plate. The solutions are mixed by pipetting and expelling 50  $\mu\text{L}$ , five times, within the same well. The Trilux plate is

covered with clear film and read on a 1450 MicroBeta Trilux liquid scintillation and luminescence counter (Wallac) with a color/chemical quench and dpm correction.

In order to determine the  $IC_{50}$  values, the data are analyzed on a spreadsheet. The analysis requires a correction for the background luminescence that is accomplished by subtracting the dpm values of wells without  $^3H$  substrate from the experimental wells. The corrected dpm values along with the concentrations of the compounds are used to calculate  $IC_{50}$  using the user-defined spline function. This function utilizes linear regression techniques between data points to calculate the concentration of compounds that produced 50% inhibition. The results are shown in Table B2.

**Example B3**

The A549 non-small cell lung human tumor cell line is purchased from the American Type Culture Collection, Rockville, MD. The cell line is free of *Mycoplasma* contamination (Rapid Detection System by Gen-Probe, Inc., San Diego, CA) and viral contamination (MAP testing by MA BioServices, Inc., Rockville, MD). The cell line is propagated and expanded in RPMI 1640 medium containing 10% heat-inactivated FBS (Life Technologies, Grand Island, NY). Cell expansions for implantation are performed in cell factories (NUNC, purchased from Fisher Scientific, Springfield, NJ). Cells are harvested at 50-90% confluency, washed once with HBSS containing 10% FBS, and suspended in 100% HBSS.

Outbred athymic (*nu/nu*) female mice ("Hsd:Athymic Nude-nu" from Harlan Sprague Dawley, Indianapolis, IN) are anesthetized with Metofane (Mallinckrodt Veterinary, Inc.,

Mundelein, IL), and 100  $\mu$ L of the cell suspension containing  $1 \times 10^7$  cells is injected subcutaneously into the right axillary (lateral) region of each animal. Tumors are allowed to grow for about 20 days until a volume of  $\sim 100 \text{ mm}^3$  is achieved. At this point, mice bearing tumors with acceptable morphology and size are sorted into groups of eight for the study. The sorting process produces groups balanced with respect to mean and range of tumor size. Antitumor activity is expressed as % T/C, comparing differences in tumor volumes for treatment group (T) to vehicle control group (C). Regressions are calculated using the formula:  $(1 - T/T_0) \times 100\%$ , where T is the tumor volume for the treatment group at the end of the experiment, and  $T_0$  is the tumor volume at the beginning of the experiment.

CMD1 is administered intravenously, once daily 5x/week for three weeks, at doses of 10, 25, 50, or 100 mg/kg. The final DMSO concentration is 10%. Each test group has eight mice. Tumors are measured, and individual animal body weights recorded. Table B3 shows the results on the 41<sup>st</sup> day.

**Example B7**

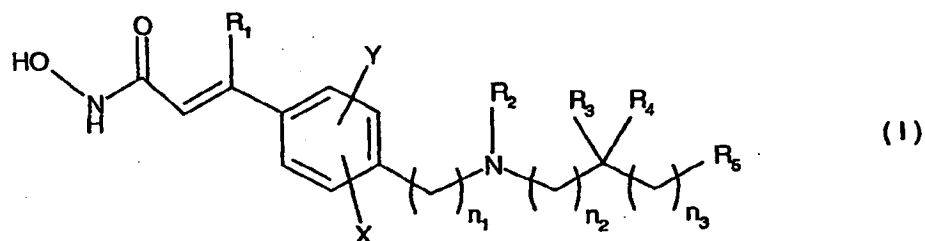

Annexin V binding was used as a marker for the early stages of apoptosis. A549, HCT116 and Normal Dermal Human Fibroblasts (NDHF) cells are treated separately with four compounds (CMD1, CMD2, CMD3 and CMD4) for 24 or 48 hours, stained with annexin V and compared to cells treated similarly with vehicle (DMSO). Cells are examined by fluorescence microscopy. Those undergoing apoptosis exhibit green fluorescent membrane staining. Viability is assessed by the counterstain, propidium iodide. Cells detected by red fluorescence are not viable. A small percentage of A549 and the majority of HCT116 cells exhibit cell surface staining with annexin V after 24 hour exposure to each of the four compounds. After 48 hour treatment, the majority of the A549 and HCT116 stain with annexin V and/or propidium iodide indicating that the compounds induce apoptotic cell death. In contrast, NDHF cells do not show noticeable annexin V staining after 24 hour exposure and limited annexin V staining with CMD3 after 48 hour. These data show that

NDHF cells predominantly underwent non-lethal growth arrest upon compound treatment, consistent with the cell cycle profile.

The staining results demonstrate that the hydroxamate compounds of the present invention cause tumor cells to die by apoptosis, while causing normal fibroblast to predominantly undergo cell cycle arrest, clearly demonstrating the selective efficacy of the present compounds.
